CASE STUDY 1: TARGETING MEASLES VACCINE OUTREACH

Danielle works at a local public health department in Stearns County, Minnesota, where she monitors vaccine-preventable disease risk and coordinates outreach with schools and community partners. Although no measles cases have been reported locally, recent outbreaks in neighboring states have raised concern about potential spread into under-vaccinated communities.

Her department has limited funding for MMR vaccination efforts, making broad, county-wide outreach infeasible. Instead, resources must be targeted to areas at highest risk.

Danielle uses the *Midwest EpiView: MMR Coverage and Measles* dashboard to examine school and child care MMR coverage in her county. While overall county coverage appears high, she observes substantial variability across schools, with some falling below the 95% herd immunity threshold. She then explores the proximity map and summary figures to identify schools in the lowest coverage percentiles, revealing clusters of under-vaccinated schools in specific areas.

Danielle focuses on a group of nearby elementary schools and child care centers with consistently low coverage, indicating potential for localized transmission if measles is introduced. Using these findings, Danielle develops a targeted outreach strategy to prioritize schools and child care centers with the lowest coverage, coordinate with administrators on immunization and exemption policies, partner with healthcare providers for local vaccination clinics, and develop targeted messaging to address hesitancy and exemptions.

Public Health Impact: By using school-level data rather than county averages, Danielle identifies hidden pockets of vulnerability and allocates limited resources more effectively to reduce outbreak risk.
